Introduction

This Mathematics Applications book was written to help you get the most from your HP-33E calculator. The programs were chosen to provide useful calculations for many of the common problems encountered in mathematics.

They will provide you with immediate capabilities in your everyday calculations and you will find them useful as guides to programming techniques for writing your own customized software.

You will find general information on how to key in and run programs under "A Word about Program Usage" in the Applications book you received with your calculator.

We hope that this Mathematics Applications book will be a valuable tool in your work and would appreciate your comments about it.

Algebra and Number Theory

Quadratic Equation

The roots x_1, x_2 of

$$ax^2 + bx + c = 0$$

are given by

$$x_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

If

$$D = (b^2 - 4ac)/4a^2$$

is positive or zero, the roots are real. In these cases, better accuracy may sometimes be obtained by first calculating the root with the larger absolute value:

If

$$-\frac{b}{2a} \geq 0, \quad x_1 = -\frac{b}{2a} + \sqrt{D}$$

If

$$-\frac{b}{2a} < 0, \quad x_1 = -\frac{b}{2a} - \sqrt{D}$$

In either case,

$$x_2 = \frac{c}{x_1 a}$$

If $D < 0$, the roots are complex, being

$$u \pm iv = \frac{-b}{2a} \pm \frac{\sqrt{4ac - b^2}}{2a} i$$

Complex Arithmetic (+, -, ×, ÷)

Let $a_1 + ib_1$ and $a_2 + ib_2$ be two complex numbers. The arithmetic operations +, -, ×, ÷ are defined as follows:

- +, addition

$$(a_1 + ib_1) + (a_2 + ib_2) = (a_1 + a_2) + (b_1 + b_2)i$$

- , subtraction

$$(a_1 + ib_1) - (a_2 + ib_2) = (a_1 - a_2) + (b_1 - b_2)i$$

- ×, multiplication

$$(a_1 + ib_1) \times (a_2 + ib_2) = r_1 r_2 e^{i(\theta_1 + \theta_2)}$$

- ÷, division

$$\frac{(a_1 + ib_1)}{(a_2 + ib_2)} = \frac{r_1}{r_2} e^{i(\theta_1 - \theta_2)}, a_2 + ib_2 \neq 0$$

where $r_1 e^{i\theta_1}$ is the polar representation of $a_1 + ib_1$ and $r_2 e^{i\theta_2}$ is the polar representation of $a_2 + ib_2$. In each case let the answer be $x + iy$.

After a calculation is finished x is stored in R_0 as well as the X-register and y is stored in R_1 as well as the Y-register. In this way arithmetic operations can be chained together.

Complex Functions (|z| , zⁿ, and z^{1/n})

A complex number $z = x + iy$ has polar representation $r e^{i\theta}$. The formulas used to evaluate the given functions are as follows:

$$|z| = r = \sqrt{x^2 + y^2}$$

$$z^n = r^n e^{in\theta} \quad n = \pm(1, 2, 3, \dots)$$

$$z^{1/n} = r^{1/n} e^{i\left(\frac{\theta}{n} + \frac{360k}{n}\right)}, k = 0, 1, \dots, n-1$$

The answer is represented by $u + iv$

Determinant and Inverse of a 2×2 Matrix

Let $A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ be a 2×2 matrix.

The determinant of A denoted by Det A or $|A|$ is evaluated by the following formula:

$$\text{Det } A = a_{22} a_{11} - a_{12} a_{21}$$

Also, the program evaluates the multiplicative inverse A^{-1} of A. The following formula is used: (A^{-1} exists only when $|A| \neq 0$).

$$A^{-1} = \begin{bmatrix} a_{22}/\text{Det } A & -a_{12}/\text{Det } A \\ -a_{21}/\text{Det } A & a_{11}/\text{Det } A \end{bmatrix} = A'$$

Simultaneous Equations in Two Unknowns

Let $ax + by = e$

and $cx + dy = f$

be a system of two equations in two unknowns. Cramer's Rule is used to find the solution.

$$x = \frac{\begin{vmatrix} e & b \\ f & d \end{vmatrix}}{\begin{vmatrix} a & b \\ c & d \end{vmatrix}} = \frac{ed - bf}{ad - bc} \quad y = \frac{\begin{vmatrix} a & e \\ c & f \end{vmatrix}}{\begin{vmatrix} a & b \\ c & d \end{vmatrix}} = \frac{af - ec}{ad - bc}$$

If $ad - bc = 0$ the calculator displays *Error 0*. In this case no solution or no unique solution exists.

Number in Base b to Number in Base 10

This program consists of two subprograms. The first changes the integer part of a number in base b to a number in base 10.

$$I_{10} = i_n i_{n-1} \dots i_2 i_1 = i_n b^{n-1} + i_{n-1} b^{n-2} + \dots + i_2 b + i_1$$

This is evaluated in the form

$$b (\dots (b (i_n b + i_{n-1}) + i_{n-2}) + \dots) + i_2) + i_1$$

The second subprogram changes the fraction part of a number in base b to a number in base 10.

$$F_{10} = f_1 f_2 \dots f_m = f_1 b^{-1} + f_2 b^{-2} + \dots + f_m b^{-m}$$

Together the two programs can convert any number in base b to a number in base 10. Zeros must be entered in their proper place.

Number in Base 10 to Number in Base b

This program will convert any positive number in base 10, N_{10} , to a number in base b , N_b , where $2 \leq b \leq 100$. The algorithm used is an iterative one which adds one more digit to N_b at each iteration. The program pauses as each new N_b is calculated to display successive approximations to the final answer. When the displayed value of N_b has reached the accuracy desired by the user, he should press $\boxed{R/S}$ to halt the program, then $\boxed{RCL} 3$ to display N_b .

Notes:

- When the base b is such that $11 \leq b \leq 100$, two display positions are allocated to each digit of N_b . Begin partitioning to the right and to the left of the decimal point. For example, 41106.12 in base 16 stands for 4B6.C.
- If the calculation is terminated with all 9's on the display, it means the machine is overflowed and the range of machine has been exceeded.

Vector Cross Product

If $A = (a_1, a_2, a_3)$ and $B = (b_1, b_2, b_3)$ are two three dimensional vectors then the cross product of A and B is denoted by $A \times B$ and is calculated as follows:

$$A \times B = \begin{pmatrix} \begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix}, - \begin{vmatrix} a_1 & a_3 \\ b_1 & b_3 \end{vmatrix}, \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix} \end{pmatrix} =$$

$$(a_2 b_3 - a_3 b_2, a_3 b_1 - a_1 b_3, a_1 b_2 - a_2 b_1)$$

Let the solution be represented by (c_1, c_2, c_3) .

Angle Between, Norm, and Dot Product of Vectors

Let $\vec{a} = (a_1, a_2, \dots, a_n)$ and $\vec{b} = (b_1, b_2, \dots, b_n)$ be two vectors.

The norm of \vec{a} is denoted by $|\vec{a}|$ and is calculated by the following formula:

$$|\vec{a}| = \sqrt{a_1^2 + a_2^2 + \dots + a_n^2}$$

similarly,

$$|\vec{b}| = \sqrt{b_1^2 + b_2^2 + \dots + b_n^2}$$

The dot product of \vec{a} and \vec{b} is denoted by $\vec{a} \cdot \vec{b}$ and is calculated by the following formula:

$$\vec{a} \cdot \vec{b} = a_1 b_1 + a_2 b_2 + \dots + a_n b_n$$

The angle between \vec{a} and \vec{b} is denoted by θ and is calculated by the following formula:

$$\theta = \cos^{-1} \left(\frac{\vec{a} \cdot \vec{b}}{|\vec{a}| \cdot |\vec{b}|} \right)$$

The angle is calculated in any angular mode. When calculated in degrees, decimal degrees are assumed.

Numerical Methods

Newton's Method Solution to $f(x) = 0$

This program uses Newton's method to find a solution for $f(x) = 0$, where $f(x)$ is specified by the user.

The user must define the function $f(x)$ by keying into program memory the keystrokes required to find $f(x)$, assuming x is in the X-register. 20 program steps are available for defining $f(x)$; the program only uses registers R_0 through R_4 , the rest of the registers are available to the user.

The user must provide the program with an initial guess, x_1 , for the solution. The closer the initial guess is to the actual solution, the faster the program will converge to an answer. The program will halt when two successive approximations for x , say x_i and x_{i+1} , are within a tolerance ϵ , i.e., when $|x_{i+1} - x_i| < \epsilon$. The value for ϵ must be input by the user. In general a reasonable value for ϵ might be $10^{-6} x_1$.

Equations:

The basic formula used by Newton's method to generate the next approximation for the solution is

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)}$$

This program makes a numerical approximation for the derivative $f'(x)$ to give the following equation:

$$x_{i+1} = x_i - \delta_i \left[\frac{f(x_i + \delta_i)}{f(x_i)} - 1 \right]^{-1}$$

where: $\delta_i = 10^{-5} x_i$

Notes:

1. After the routine has finished calculating, the last value of $f(x)$ may be displayed by pressing **RCL** 4. If this value is not close enough to zero, the program may be run again with a smaller value for ϵ .
2. The user can watch the function converge to zero by making a slight change in the program. If the **9** **NOP** in line 45 is replaced by an **f** **PAUSE**, the program will pause during each iteration, displaying successive values of $f(x)$ which should be converging to zero. To make this change to a program that has already been keyed in, perform the following operations:

1. Press **GTO** 44
2. Switch to PRGM
3. Press **f** **PAUSE**
4. Switch to RUN
5. Press **f** **PRGM**

Example:

An equation often solved by gear designers is

$$\tan x - x - I = 0$$

where x is an angle in radians and I is the involute of x . Find the angle x_0 corresponding to an involute of 0.0324.

Note:

Since a gear designer might want to calculate x for several values of I , it will be simpler to store I in R_7 for use by the function $f(x)$.

Solution:

$$x_0 = 25.62^\circ$$

$$\text{Last } f(x) = 1.30 \times 10^{-9}$$

Numerical Integration, Simpson's Rule

Let x_0, x_1, \dots, x_n be equally spaced points such that $x_i = x_0 + ih$ for $i = 0, 1, 2, \dots, n$ at which corresponding values $f(x_0), f(x_1), \dots, f(x_n)$ of a function $f(x)$ are known. This function need not be known explicitly but if it is, these values can be found previously by writing the function into memory and evaluating at the various points. n must be an even positive integer.

$$\int_{x_0}^{x_n} f(x) dx \approx \frac{h}{3} [f(x_0) + 4f(x_1) + 2f(x_2) + \dots + 4f(x_{n-3}) + 2f(x_{n-2}) + 4f(x_{n-1}) + f(x_n)].$$

Let the solution be indicated by I.

Circle Determined by Three Points

This program calculates the center (x_0, y_0) and radius (r) of a circle given three non-collinear points.

The equation of a circle is:

$$(x - x_0)^2 + (y - y_0)^2 = r^2$$

x_0 and y_0 are solved from:

$$\begin{bmatrix} (x_1 - x_3) & (y_1 - y_3) \\ (x_1 - x_2) & (y_1 - y_2) \end{bmatrix} \begin{bmatrix} x_0 \\ y_0 \end{bmatrix} =$$

$$\begin{bmatrix} \frac{1}{2} [(x_1 - x_3)(x_1 + x_3) + (y_1 - y_3)(y_1 + y_3)] \\ \frac{1}{2} [(x_1 - x_2)(x_1 + x_2) + (y_1 - y_2)(y_1 + y_2)] \end{bmatrix}$$

$$\text{and } r = \sqrt{(x_1 - x_0)^2 + (y_1 - y_0)^2}$$

Example 1:

Find the equation of the circle that goes through the three points (1, 1) (3.5, -7.6), (12, 0.8).

Solution 1:

Center = (6.45, -2.08), r = 6.26

$$\text{Equation: } (x - 6.45)^2 + (y + 2.08)^2 = (6.26)^2$$

Intersection of Line and Line

This program calculates the point of intersection (x_p , y_p) of two lines, each of them is specified by two points, i.e., (x_1, y_1) , (x_1', y_1') and (x_2, y_2) , (x_2', y_2') . x_p and y_p are calculated from the equation of straight line $y = x \tan \theta + c$. i.e., by solving:

$$\begin{bmatrix} 1 & -\tan \theta_1 \\ 1 & -\tan \theta_2 \end{bmatrix} \begin{bmatrix} y_p \\ x_p \end{bmatrix} = \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}$$

“Error 0” will be displayed if two lines have the same slope, i.e., if there are either parallel or overlapping.
